

# Semisimple algebras and Wedderburn's Theorem

## Defn

Def<sup>n</sup>: A ring  $A$  is called semisimple if every finitely generated  $A$ -module is semisimple.

Theorem 1:  $A$  is semisimple if and only if the regular module  $A$  is semisimple. Furthermore, in this case  $A$  is both Artinian and Noetherian.

Proof: If  $A$  is semisimple then the regular module is semisimple, by def<sup>n</sup>. Conversely, if the regular module is semisimple then any free module is semisimple. Hence any finitely gen<sup>d</sup> module  $M$  is semisimple, as it is a quotient of a finite rank free module  $\bigoplus_{i=1}^n A \rightarrow M$ . [Prop 9, Smalgs].

In any case any finitely generated semisimple module is necessarily a finite sum of simples, and thus admits a composition series. In particular,  $A$  itself admits a composition series, and is therefore both Artinian and Noetherian [Thm 7 & Lemma 10, Fuchs].

# - I's Semisimplicity via proj/inj

**Def<sup>1</sup>:** An  $A$ -module  $M$  is called projective (resp. injective) if the functor  $\text{Hom}_A(M, -)$  (resp.  $\text{Hom}_A(-, M)$ ) preserves exact sequences.

**Proposition 3:** For an Artinian + Noether ring  $A$ , TFAE:

- $A$  is semisimple,
- All finitely generated  $A$ -modules are projective.
- All finitely generated  $A$ -modules are injective.

Let's take a second to think about this. For any exact sequence  $0 \rightarrow L' \xrightarrow{i} N \xrightarrow{\pi} L \rightarrow 0$  and  $A$ -mod  $M$ , we have the inclusion of  $Z_{\text{mod}}$

$$i_* : \text{Hom}_A(M, L') \rightarrow \text{Hom}_A(M, N)$$

$$f \mapsto i \circ f$$

and the image of this inclusion is the kernel of the map  $\pi_* : \text{Hom}_A(M, N) \rightarrow \text{Hom}_A(M, L)$ .

This is to say, we obtain a left exact sequence

$$0 \rightarrow \text{Hom}_A(M, L') \xrightarrow{i_*} \text{Hom}_A(M, N) \xrightarrow{\pi_*} \text{Hom}_A(M, L)$$

for free.

Similarly, the functor  $\text{Hom}_A(-, M)$  applied to such an exact sequence produces a left exact sequence

$$0 \rightarrow \text{Hom}_A(L, M) \xrightarrow{\pi^*} \text{Hom}_A(N, M) \rightarrow \text{Hom}_A(L', M).$$

$$f \mapsto f\pi, \quad f' \mapsto f' \circ \iota = f'|_{L'}.$$

So to say  $M$  is projective is to say that any surjection  $\alpha: N \rightarrow L$  and arbitrary  $f: M \rightarrow L$  admits some  $\tilde{f}: M \rightarrow N$  which completes a diagram

$$\begin{array}{ccc} \tilde{f} & M & \\ & \downarrow \alpha & \\ & N \rightarrow L & \end{array}$$

To say  $M$  is injective says that every inclusion  $i: L' \rightarrow N$  and map  $g: L' \rightarrow M$  admits some  $\tilde{g}: N \rightarrow M$  for which we have a diagram

$$\begin{array}{ccc} & L' & \rightarrow N \\ & \downarrow i & \\ \tilde{g} & N & \xrightarrow{\quad} M \end{array}$$

Example: The regular module  $A$  is projective over  $A$ .

Example:  $\mathbb{Q}$  is an injective  $\mathbb{Z}$ -module.

Example: The regular module  $k[X]/(x^n)$  is injective over  $k[X]/(x^n)$ .

Proof of prop 3:  $(a) \Rightarrow (b)$  and  $(c)$  If  $A$  is semi-simple then any exact sequence

$$0 \rightarrow L' \rightarrow N \rightarrow L \rightarrow 0$$

splits. We can then use the implied splitting maps  $s: L \rightarrow N$  and  $t: N \rightarrow L'$  to lift any map  $f: M \rightarrow L$  to a map  $f \circ s: M \rightarrow N$  and any map  $g: L' \rightarrow M$  to  $\bar{g} = g \circ t: N \rightarrow M$ . So we see any  $A$ -module  $M$  is both projective and injective in this case.

$(b) \Rightarrow (a)$  If all modules are projective, take any module  $N$  and a surjective  $\pi: N \rightarrow L$  onto simple  $L$ . Then we can lift the identity  $\text{id}: L \rightarrow L$  along  $\pi$  to get a map  $s: L \rightarrow N$  with  $\pi \circ s = \text{id}_L$ , and hence split  $N$  as

$$N = L \oplus N' \text{ for } N' = \ker(\pi).$$

Noting that  $\text{length}(N') = \text{length}(N) - 1$ , we see by induction on the length that  $N$  is semi-simple.

Since  $N$  was chosen arbitrarily, we found that  $A$  is semi-simple.

$(c) \Rightarrow (a)$  Similar. 

## ~ II. Examples of semisimple algebras: Maschke's Theorem

Take  $k$  a field.

Let  $G$  be a (finite) group, and consider the group alg.  $k[G]$ . For any  $G$ -rep  $M$  (over  $k$ ) we define the invariants

$$M^G = \{ m \in M : g \cdot m = m \text{ at all } g \in G \} \subseteq M.$$

Obviously any map of  $G$ -reps preserves invariants, i.e.

$$g \cdot f(m) = f(g \cdot m) = f(m) \text{ whenever } m \in M^G$$

and  $f: M \rightarrow N$  is a map of  $G$ -reps. Hence we have the invariant functor

$$-^G: k[G\text{-mod}] \rightarrow \text{Vect}_k.$$

For  $k = \mathbb{C}$  and the trivial  $G$ -rep, we have

$$M^G = M^1 \quad \text{so that any}$$

module map  $M \rightarrow M^1$  has image in the  $G$ -invariant  $M^G \subseteq M$ .

Lemma 4: For any group  $G$  and field  $k$ , and  $k[G]$ -module  $M$ , there is a natural isomorphism

$$\varphi_1: \text{Hom}_G(k, M) \xrightarrow{\sim} M^G, \quad f \mapsto f(1).$$

Proof: Apparent.

~~□~~

~ II.1/2 A little more

For any group  $G$ , and  $G$ -reps  $M$  and  $N$ , we have the  $G$ -action on  $\text{Hom}_K(M, N)$  given by,

$$g \cdot f = \{ m \mapsto g f(g^{-1} \cdot m) \}.$$

This gives the vector space  $\text{Hom}_K(M, N)$  the structure of a  $G$ -rep /  $KG$ -module.

Lemma 3: The invariant  $\text{Hom}_K(M, N)^G$  are precisely the " $KG$ -module maps".

$$\text{Hom}_{KG}(M, N) = \text{Hom}_K(M, N)^G.$$

Proof: If  $f: M \rightarrow N$  is a  $KG$ -module map then  $g f(g^{-1} \cdot m) = g g^{-1} f(m) = f(m)$  at all  $m$  in  $M$ . Thus  $f$  is  $G$ -invariant in  $\text{Hom}_K(M, N)$ . Conversely, if  $f: M \rightarrow N$  is  $G$ -invariant then at all  $m$  in  $M$  and  $g$  in  $G$  we have

$$f(g \cdot m) = g f(g^{-1}(g \cdot m)) = g f(m).$$

So  $f$  is a  $KG$ -module map. □

Corollary 4: For any finite group  $G$ , and field

$u$ ,  $uG$  is a semisimple  $uG$ -module if and only if the  $uG$ -module  $u = uG$  is projective.

Proof: If  $uG$  is semisimple then  $u$  is projective, by Proposition 3. Conversely, suppose  $u$  is projective. Then the invariant factor  $\text{Hom}_G(u, -) \cong -^G$  preserves exact sequences. Hence for an arbitrary exact sequence

$$0 \rightarrow L' \rightarrow M \rightarrow L \rightarrow 0$$

and arbitrary  $M$ , we have the exact sequence

$$0 \rightarrow \text{Hom}_G(M, L') \rightarrow \text{Hom}_G(M, M) \rightarrow \text{Hom}_G(M, L) \rightarrow 0$$

(since all vector spaces are proj over  $u$ , or whatever) and applying invariant we see that the sequence

$$0 \rightarrow \text{Hom}_G(M, L') \rightarrow \text{Hom}_G(M, M) \rightarrow \text{Hom}_G(M, L) \rightarrow 0$$

is exact. Thus,  $M$  is projective. Since  $M$  was chosen arbitrarily we find that  $uG$  is semisimple, by Proposition 3. □

## $\hookrightarrow$ 4 $\frac{2}{3}$ Maschke's Theorem

Theorem (Maschke): Let  $G$  be a finite group and  $k$  be a field. If  $\text{char}(k) \nmid |G|$ , then

$\hookrightarrow G$  is a semisimple ring/algebra.

Proof: Since  $|G|$  is a unit in  $\mathbb{K}$  we have the element

$$e_{\text{triv}} = \frac{1}{|G|} \sum_{g \in G} g \in \mathbb{K}G.$$

Note that for any group element  $h \in G$ ,

$$h \cdot e_{\text{triv}} = e_{\text{triv}} \quad (*)$$

and for any invariant vector  $v \in V^G$  in a  $G$ -rep  $V$  we have

$$e_{\text{triv}} \cdot v = \frac{1}{|G|} \sum_{g \in G} v = v.$$

Now, suppose we have a surjective  $\mathbb{K}G$ -module map  $\pi: N \rightarrow L$  and a map of  $\mathbb{K}G$ -modules

$$f: \mathbb{K} = \mathbb{K}e_{\text{triv}} \rightarrow L.$$

Take  $u' \in N$  an arbitrary preimage of  $f(e)$  along  $\pi$ , and let  $u = e_{\text{triv}} \cdot u'$ . Then by

(\*) we have  $g \cdot u = g \cdot e_{\text{triv}} u' = u$  at all

$g \in G$ , giving  $u \in V^G$ , and also

$$\begin{aligned} \pi(u) &= \pi(e_{\text{triv}} \cdot u') = e_{\text{triv}} \cdot \pi(u') \\ &= e_{\text{triv}} \cdot f(e) = f(e). \end{aligned}$$

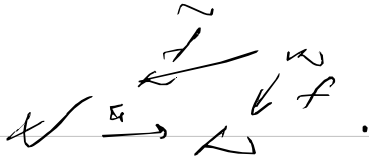

So  $u \in \pi^{-1}(f(e))$  is a  $G$ -invariant lift of  $f(e)$ , and the

map of  $\mathbb{K}G$ -modules

$$\tilde{f}: \mathbb{K} \rightarrow V^G, \quad \tilde{f}(e) = u$$

completes a diagram

To see that the trivial module  $k$  is projective over  $uG$ , and hence that  $uG$  is semisimple by Corollary 4. □

HW: The converse to Maschke is also true.  
If  $\text{char}(k) \mid |G|$  then  $uG$  is not semisimple.

Example: For any finite group  $G$ ,  
 $\mathbb{Q}G, \mathbb{R}G, \mathbb{C}G$   
are all semisimple algebras. So, like,

$\mathbb{Q}\mathbb{Z}/p\mathbb{Z}$  is semisimple

$\mathbb{Q}S_n$  is semisimple,  $\mathbb{C}S_3$  is semisimple

etc.

Ex:  $\mathbb{F}_p\mathbb{Z}/n\mathbb{Z}$  is nonsemisimple (and only if  $p \mid n$ ).

$\overline{\mathbb{F}}_5 D_7$  is semisimple.  $\overline{\mathbb{F}}_7 D_2$  is nonsemisimple.

Question: For  $S_n$ , for example, can we classify  $S_n$ -reps over  $\mathbb{C}$  up to isomorphism?

Can we say how many of them there are?

Can we determine the dimensions that occur?

# ~ III Artin-Wedderburn

Lemma 5: For any division algebra  $D$ ,

i)  $D^{op}$  is also a division algebra

ii) There is  $Z(D)$ -algebra isomorphism

$$M_n(D) \xrightarrow{\sim} M_n(D^{op})^{op}.$$

Proof: (i) Apparent. (ii) Take the transpose. ~~Q~~

Proposition 6: For any semisimple module

$$M \cong \bigoplus_{i=1}^r n_i L_i \text{ over a } k\text{-alg } A$$

with the  $L_i$  distinct, and  $D_i = \text{End}_A(L_i)$ ,

there is an isomorphism of  $k$ -algebras

$$\prod_{i=1}^r M_{n_i}(D_i) \xrightarrow{\sim} \text{End}_A(M).$$

Proof: From any explicit choice of module  $\cong$   
 $f: \bigoplus_i n_i L_i \xrightarrow{\sim} M$  we get an alg. isom

$$\begin{aligned} \text{Alg } f: \text{End}_A(M) &\xrightarrow{\sim} \text{End}_A\left(\bigoplus_i n_i L_i\right) \\ \xi &\mapsto f \circ \xi \circ f^{-1}. \end{aligned}$$

So we may assume  $M = \bigoplus_{i=1}^r n_i L_i$ . Now  
 for  $M_i = n_i L_i \leq M$  any module map  
 $\xi: M \rightarrow M$  sends  $M_i$  into  $M_i$ ,

by Schur's Lemma say, so that

$$\bar{\Sigma} = \begin{bmatrix} \xi_1 & & 0 \\ & \ddots & \\ 0 & & \xi_r \end{bmatrix} : M = \bigoplus_{i=1}^r M_i \rightarrow M = \bigoplus_{i=1}^r M_i$$

for  $\xi_i = \xi|_{M_i}$ . So we have

$$\text{End}_\Lambda(M) = \prod_{i=1}^r \text{End}_\Lambda(M_i). \quad (*)$$

At fixed  $M_i$  now take

$$\iota_i : L_i \rightarrow M_i \text{ and } p_i : M_i \rightarrow L_i$$

the inclusion and projection onto the  $i$ -th copy of  $L_i$  in the given decomp  $M_i = \bigoplus_{j=1}^{n_i} L_i$  we have

$$\xi = \sum_{st} \xi_{st} \quad , \quad \xi_{st} = \iota_s p_s \xi_{it} p_t$$

since

$$\text{id}_{M_i} = \sum_t \iota_t p_t$$

We note that composition satisfies

$$\xi' \circ \xi = \sum_{s,t,u} \xi'_{su} \circ \xi_{ut}$$

Hence, for

$$\bar{\xi}_{st} = p_s \xi_{it} \in \text{End}_\Lambda(L_i) = D_i$$

we get an explicit algebra isomorphism

$$\begin{aligned} \text{End}_\Lambda(M_i) &\xrightarrow{\cong} M_{n_i}(D_i) \\ \xi &\mapsto [\bar{\xi}_{ij}] \end{aligned}$$

Taking this into (\*) gives

$$\text{End}_A(A) \cong \overline{\prod_{i=1}^r M_{n_i}(D_i)}.$$

Theorem (Artin-Wedderburn Thm): For any semisimple  $k$ -algebra  $A$ , there is a pair of  $k$ -algs

$$A \cong \overline{\prod_{i=1}^r M_{n_i}(D_i)}$$

for some division algebras  $D_i$ .

Proof: Write  $D_i = \text{End}_A(L_i)^{\text{op}}$  for a complete list of simple  $A$ -modules  $L_1 \rightarrow L_r$ , up to isomorphism, and  $\psi_i = [L_i : A]$ , to get

$$\begin{aligned} A &\xrightarrow[\text{HW}]{} \text{End}_A(A) \xrightarrow[\text{Prop 6}]{} \overline{\prod_{i=1}^r M_{n_i}(D_i^{\psi_i})^{\text{op}}} \\ &\xrightarrow[\text{Lemma 5}]{} \overline{\prod_{i=1}^r M_{n_i}(D_i)}. \end{aligned}$$

Remark: Recall that for any division ring  $D$  the corresponding matrix algebra  $M_n(D)$  is semisimple, of any  $n$ . Hence so is a product  $\prod_{i=1}^r M_{n_i}(D_i)$ . So the Artin-Wedderburn classifies semisimple algs completely, up to a classification of div. algs.

Classification of division algebras, in general, is an interesting problem, which is impossible to achieve in general. (E.g. Contains the classification of all fields.)

Corollary 7: Suppose  $K = \bar{K}$  is alg closed field, and that  $A$  is a finite-dimensional, semisimple  $K$ -algebra. Then there is a  $K$ -algebra isomorphism

$$A \cong \prod_{i=1}^r M_{n_i}(K). \quad (*)$$

Proof: Each division alg appearing in the AW decomp

$$A \cong \prod_i M_{n_i}(D_i)$$

is a finite-dim div. alg over  $K$ . Since there are no such div algs besides  $K$  itself, by alg closure [Lemma 3, Serre], we conclude

$$A \cong \prod_i M_{n_i}(K).$$

Note that, since we know the unique simple  $M_n(K)$ -module is of dim  $n$ , naturally  $\dim_K(K^n) = n$ , we see that is  $(*)$

$$\{n_1, \dots, n_r\} = \{\dim_K(L_1), \dots, \dim_K(L_r)\},$$

where we run across all distinct simple  $L_i$  for  $A$ .

Example: We saw in HW that  $S_3$  has two 1-dim reps are  $\mathbb{C}$ , and one 2-dim simple rep. Since

$$\dim S_3 = 6 = 1 + 1 + 2^2$$

This gives the HW decomp

$$\mathbb{C} S_3 \cong \mathbb{C} \times M_2(\mathbb{C}) \times \mathbb{C}$$

You can deduce from AW that this isomorphism can be realized via the action map

$$\begin{array}{ccc} \mathbb{C} S_3 & \begin{array}{l} \nearrow \\ \longrightarrow \\ \searrow \end{array} & \begin{array}{l} \text{End}_{\mathbb{C}}(\mathbb{C}_{\text{triv}}) \\ \text{End}_{\mathbb{C}}(\mathbb{C}^{(2,1)}) \\ \text{End}_{\mathbb{C}}(\mathbb{C}_{\text{sign}}) \end{array} \\ & \text{action} & \end{array} .$$

## ~ IV Splitting division algebras

Let me record a fundamental theorem which we don't prove. Below we employ the following basic construction:

Given a comm. ring map  $K \rightarrow \mathcal{K}$  and a  $\mathcal{K}$ -alg  $A$ ,  $K \otimes_{\mathcal{K}} A$  inherits a unique  $\mathcal{K}$ -alg structure for which the inclusion  $K \rightarrow K \otimes_{\mathcal{K}} A$ ,  $c \mapsto c \otimes 1$ , is the unit map and  $A \rightarrow K \otimes_{\mathcal{K}} A$ ,  $a \mapsto 1 \otimes a$ , is a ring map. We have the expected multiplication on  $K \otimes_{\mathcal{K}} A$

$$\left( \sum_i c_i \otimes a_i \right) \cdot \left( \sum_j c_j \otimes a_j \right) = \sum_{ij} c_i c_j \otimes a_i a_j .$$

**Theorem 8:** Let  $D$  be a division algebra which is finite over its center  $K = Z(D)$ .

- For any field extension  $K \rightarrow K_0$  the base change  $K_0 \otimes_K D$  is a semisimple  $K_0$ -algebra.
- $\bar{K} \otimes_K D \cong M_n(\bar{K})$ , as a  $\bar{K}$ -alg, for some  $n$ .
- There is a finite field extension  $K \rightarrow K_0$  for which  $K_0 \otimes_K D \cong M_n(K_0)$ , as a  $K_0$ -alg.

**Proof:** (a) We take for granted. (b) Follows by (a) and Artin-Wedderburn for finite semisimple  $\bar{K}$ -alge. (c) We have for each matrix element

$$E_{ij} \in \bar{K} \otimes_K D \cong M_n(\bar{K})$$

$$E_{ij} = \sum_{t=1}^{m_{ij}} \alpha_t^{ij} \otimes d_t$$

for some  $\alpha_t^{ij} \in \bar{K}$  and  $d_t \in D$ . Take

$$K_0 = K(\alpha_t^{ij} : 1 \leq i, j \leq n, t \leq m_{ij}) \text{ to get}$$

$$K_0 \otimes_K D \cong M_n(K_0) \subseteq M_n(\bar{K}). \quad \blacksquare$$

**Rem:** We need the assumption  $K = Z(D)$  for (a) - (c) to hold.

Any field extension  $K \rightarrow K_0$  s.t.  $K_0 \otimes_K D \cong M_n(K_0)$

is called a splitting field for  $D$ .

**Corollary 9:** If  $D$  is finite over its center  $K = Z(D)$ , then  $\dim_K D = n^2$  for some  $n \in \mathbb{Z}_{>0}$ .

$H/W$

1. Let  $P$  be projective, and suppose that  $P$  decomposes as  $P \cong M \oplus M'$ . Prove that  $M$  and  $M'$  are also projective.

(b) Prove that a module  $M$  is projective if and only if  $M$  appears as a summand of a free module  $M \oplus M' \cong \bigoplus_{\lambda \in \Lambda} A$ .

2. Let  $H \rightarrow G$  be an inclusion of groups. Prove that, for  $K$  any field (or comm ring),  ${}_K G$  is a projective module over  ${}_K H$ . Specifically,  ${}_K G$  is free over  ${}_K H$ .

3. Let  $G$  be a group and  $H \leq G$  be a subgroup. If  ${}_K H$  is nonsingular, prove that  ${}_K G$  is nonsingular as well.

4. Let  $K$  be a field of characteristic  $p > 0$ . Prove that  ${}_K \mathbb{Z}/p\mathbb{Z}$  is nonsingular. You can do this for example, by producing a nonsplit extension

$$0 \rightarrow K \rightarrow V \rightarrow K \rightarrow 0$$

of the trivial module  $K = K \text{triv}$ .

5. Let  $G$  be a finite group, and suppose  $\text{char}(k) \nmid |G|$ . Prove that  $k[G]$  is nonseparable.

6. Provide an example of the following:  $D$  is a finite dimensional division algebra over a field  $k$  - so, possibly a finite field extension for example - for which the base change  $\bar{k} \otimes_k D$  is nonseparable. [Hint: we say in this case that  $D$  is not separable over  $k$ .]

(
